In this study; the incidence of toxoplasma infection and the relationship between toxoplasmosis and immunosuppressive treatment were investigated in patients with systemic lupus erythematosus (SLE). In addition, the characteristics of exacerbations in patients and the relationship between the disease activity and toxoplasmosis were determined. Exacerbations in patients with systemic lupus erythematosus were frequently characterized by fatigue (78.94%), malar rash (63.15%), renal involvement (%68.42), neurologic involvement (36.84), hematologic involvement (%68.42), positive antinukleer antibody (ANA) test (100%), positive anti-ds DNA test (84.21) and decreased levels of C3 and C4 (68.42%). Our results also suggested that the disease activity in patients with systemic lupus erythematosus might be related to acute toxoplasmosis. We may conclude that the frequency of seropositive toxoplasma IgG antibodies in patients with systemic lupus erythematosus was higher than that of controls and the risk of acute toxoplasmosis might be increased by immunosuppressive treatment. [Turk J Med Res 1996; 14(1):13-15]

Key Words: Systemic Lupus Erythematosus, Immunosuppressive therapy, Toxoplasma infection

Systemic Lupus Erythematosus is a disease of unknown etiology and characterized by inflammations of various organs and production of antibodies which are activated by nuclear, cytoplasmic or cell membran antigens (1-3).

Because the course of the disease is characterized by exacerbations and remissions, several activity indexes have been suggested to determine how serious the activity is and how we should plan the management (4-6).

Among the factors that effect the quality of life and survival in SLE patients, exacerbations and infections are known to be the most important ones. Though both SLE and toxoplasmosis have high prevalances in many populations, there have been very little number of studies on the relationship between them, besides the patients that were not immunosupressed were not involved in these studies (7,8). We investigated the frequency of toxoplasmosis in SLE patients and its relationship with immunosuppressive treatment.

MATERIALS AND METHODS

Study group involved 35 patients with SLE all of whom were followed by Gülhane Military Medical School, clinic of Internal Medicine and they had 4 or more of the criteria for SLE that was updated in 1982. Eleven of the patients had undergone immunosuppressive treatment and 19 patients had exacerbations. Lupus activity index (LAI), which was defined by Petri et al (6) was used evaluating the activity. Lupus activity index (LAI) is the aritmetical mean of the following parameters.

1. Psychiatia general assessment: 0-3 points
2. Fatigue, rash, involvement of the joints, serositis: 0-3 points for each entity. Then after the mean of total is obtained. For the involvement of joints, arthralgia: 1 point, arthritis: 2 points, limitation of the mobility: 3 points.
3. Neurological, renal, pulmonary and hematological involvement: Each of them is evaluated between 0-3 points and the highest score is taken up. Neurological involvement: It was evaluated by consultant psychicians of psychiatry and neurology.
Renal involvement was evaluated by creatininemia and clearance of creatinin.

Hematological involvement: It was evaluated as follows and the highest score is taken up.

- Hemoglobin (%): 10-12 (1 point), 8-9.9 (2 points), <8 (3 points).
- Leucocyte (mm3): 2500-4000 (1 point), 1500-2499 (2 points), <1500 (3 points).

4. Treatment with corticosteroids and cytotoxic agents: The mean value of both is taken up. The dosage of corticosteroid: 1-15 mg/day (1 point), 15-39 mg/day (2 points), >40 mg/day (3 points).

3 points for all the cytotoxic agents.

5. The mean value of the following 3 laboratory tests:
   a) Proteinuria: (+) 1 point, (++/+++ 2 points, (+++) 3 points.
   b) Anti dsDNA: For it was not measured quantitatively it was not considered while having mean values.
   c) Total hemolytic complement (instead of that, C3 and C4 were used)
      - C3 (mg%) 35-54 (1 point), 20-34 (2 points), <20 (3 points).
      - C4 (mg%) 15-19 (1 point), 13-14 (2 points), <9 (3 points).

The patient group was compared with the control group formed of healthy persons with matching age, sex and serological properties.

ANA (by IFAT in the lab. of microbiology clinic)
Anti dsDNA (by latex agglutination with LE-LATEX, Chemelix kits), toxoplasma IgG antibodies (by ELISA IgG), toxoplasma. IgM antibodies (by bioclinica ELISA IgM 48 test with bio-bak kit) were tested and the absorbances of each was determined at 490 nm in EL-311 Bio-tek enzym spectrofotometer. The result value was taken as (+) if it is greater than 1 and (-) if it is less than 1. Cut-off value of the test matches with the reference.

Statistical assessment was performed using X2 test, correlation analysis, Student-t test and Yates corrections. P values less than 0.05 were considered significant.

RESULTS

Twelve (34%) of the patients were male and 23 (66%) were female. The ratio of female/male was 2/1. Mean age was 30.28±1.74. The control group was also consisted of 12 male (34%) and 23 (66%) female and the mean age of them was 31.93±1.63. The mean duration of disease was 2.08±0.37 years and mean number of criteria in the patients was 6.0±0.26. The mean value of LAI was 0.90±0.11 (Table 1).

The number of the cases seropositive for toxoplasmosis was higher than that of controls (X2=6.93, p<0.01) 5 cases with the value >1 for toxoplasma IgM, did not vary significantly compared with the controls (X2=3.45, p<0.01). Toxoplasma IgG was <1 in two of these 5 cases (Table 2).

Immunosupressed patients (11) had longer duration of disease compared with the patients that had never taken immunosuppressive treatment (24) (p<0.05). In addition, mean toxoplasma IgM was found to be higher in immunosupressed patients (Table 3).

Between immunosupressed and not immunosupressed it was estimated that a variance for toxoplasma IgG>1 values statistically exist. Moreover, the number of the patients with toxoplasma IgM>1 was higher significantly in immunosupressed group than untreated group (X2=4.03, p<0.05). ANA positivity was similar between two groups (X2=0.13, p<0.01).

DISCUSSION

Exacarbations and infections are the leading causes of mortality and morbidity in SLE patients (9,12). Most of the studies on infections in SLE patients focus on the bacterial infections and data on opportunistic infections are derived from the case reports mostly (6,9,10,11).

Though the high prevalances of toxoplasmosis, an opportunistic infection, in communities, there are little studies on its relationship with SLE and these studies did not investigate its relationship with immunosupressed patients with SLE either (7,8).

There is only one study focused on the toxoplasmosis in SLE patients which was performed by Wilcox et al in 1990 (8). They investigated toxoplasma serology

in 50 patients and found that 51% of SLE patients and 21% of controls seropositive. There was 1 patient with positive IgM demonstrating acute infection. Eleven patients had high titrations which never observed in controls and they concluded it could not attributed to SLE. They reported the polyclonal antibody response was not the cause of the high titrations and no false positive test for ANA or RF occurred.

The frequency of seropositivity of toxoplasm IgM antibody was higher in SLE patients than that of controls statistically (14.28% and 0%, p<0.05). But the frequency of seropositivity of toxoplasm IgG was higher more significantly in SLE patients (68.7% and 34.28%, p<0.01).

The frequency of seropositivity of toxoplasm IgG antibody was not different between immunosuppressed and not immunosuppressed groups (72.72% and 66.66%, p>0.05). But the frequency of toxoplasm IgM antibody was higher in toxoplasm IgG patients than not immunosuppressed ones (36.36% and 4.16%, p<0.05).

In conclusion, we found the seropositivity of toxoplasm IgM antibody to be higher in SLE patients than that of controls and immunosuppressive treatment increases the risk of acute toxoplazmosis. In this context, we suggest the immunosuppressive treatment in SLE patients to be recommended carefully to avoid opportunistic infections such as toxoplazmosis.
