Does Total Intravenous Anaesthesia (TIVA) with Propofol-Alfentanil Attenuate the Stress Response? Comparison between TIVA and inhalation anaesthesias

PROPOFOL-ALFENTANIL İLE YAPILAN TOTAL İNTRAVENÖZ ANESTEZİ (TİVA) STRES CEVABINI ZAYIFLATIR MI? TİVA VE İNHALASYON ANESTEZİSİNİN KARŞILAŞTIRILMASI

Summary
We investigated the effects of total intravenous anaesthesia (TIVA) with propofol-alfentanil and air-oxygen mixture on the endocrine response to stress by comparing with inhalation anaesthesia (IA) using halothane and N2O-oxygen. ASA I-II 30 adult patients undergoing open uretherolithotomy divided into two groups. All the patients were premedicated with atropine 0.5 mg and diazepam 5 mg intramuscularly. In TIVA group (n=15), anaesthesia was induced with alfentanil 25 μg kg⁻¹ and propofol 2 mg kg⁻¹, and maintained with the infusion of alfentanil 10 μg kg⁻¹ for the first 10 minutes and with 0.5 μg kg⁻¹ thereafter and at the same time with propofol 10 μg kg⁻¹ for the first 10 minutes, 8 mg kg⁻¹ hour⁻¹ for the following 10 minutes and 6 mg kg⁻¹ there after. Patients were ventilated with oxygen-air mixture. In IA group (n=15), anaesthesia was induced with thiopentone 6 mg kg⁻¹, and maintained with halothane 1 % and N2O 66 % in oxygen. All patients in each group were ventilated mechanically in such a way that the value of FiO₂ would be 0.3. The so called “stress hormones” such as Cortisol, ACTH, human growth hormone (hGH), prolactin and insulin as well as blood sugar concentrations were measured the day before surgery (control), 30 and 60 minutes after intubation and 120 minutes after the end of surgery. All samples were taken between 8.00 a.m. and 12.00 a.m. In both groups, Cortisol, ACTH, prolactin and blood sugar concentrations increased significantly compared with the control values (p<0.05). hGH did not change in TIVA group. Insulin did not change in both groups. ACTH and hGH were significantly higher in IA group than TIVA group (p<0.05). We concluded that TIVA was much more capable to suppress the endocrine stress response than IA.

Key Words: Anaesthetic techniques: TIVA, Stress response

Ozet
Bu çalışmada, propofol-alfentanil ve hava-oksijen karışımı ile sağlanan total intravenöz anestezinin (TİVA)’nin stres hormonları yanıt üzerindeki etkileri, halotan ve N2O-oksijen ile sağlanan inhalasyon anestezisi (İA) ile karşılaştırılmıştır. Üreterolitotomi geçirecek ASA I-II 30 yetişkin hastaları iki gruba ayrılmış. Her iki gruptaki hastaların premedikasyonu atropin 0.5 mg ve diazepam 10 mg intramüsküler olarak yapılmıştır. TİVA grubunda (n=15), anestezinin ilk 10 dakikalık döneminde alfentanil 25 μg kg⁻¹ ve propofol 2 mg kg⁻¹ ile induksiyonu sağlandığından sonra, ilk 10 dakikalık döneminde alfentanil 10 μg kg⁻¹, 10-5 μg kg⁻¹ 1 saat sonra ve propofol 10-8-6 mg kg⁻¹ 1 saat sonra olan infüzyonlarla devam edilmiştir. Bu gruptaki hastalar oksijen-hava karışımı ile solunmuşlardır. IA grubunda (n=15), anestezinin induksiyonu tiyopenton ile 6 mg kg⁻¹, devamı ise halotan ve oksijen içinde %1 halotan ve %66 oksijen şeklinde sağlanmıştır. Her iki grupta da hastalar, FiO₂: 0.3 olarak şekilde mekanik bir ventilatör kullanarak solunmuşlardır. “Stres hormonları” olarak da bilinen kortizol, ACTH, büyüme hormonu (hGH), prolaktin, insülin ve kan şekeri kontrantasyonları, operasyonunun başında ve sonunda ölçülmiştir. Her iki grupta da kortizol, ACTH, prolaktin ve kan şekeri kontrantasyonları operasyonunun gerçekleştiği dönemde artmıştır (p<0.05). hGH, TİVA grubunda değişmedi. Insülin ise her iki grubunun değişmemiştir. ACTH ve hGH değerleri IA grubunda TİVA grubunda oldukça belirgin olarak daha yükseklik (p<0.05). TİVA’nın stres hormonları yanıtında daha iyi baskılama kapasitesine sahiptir.

Anahtar Kelimeler: Anestetik teknik: TIVA, Stres yanıt

Endocrine and metabolic changes occur in response to anaesthesia and surgical stress (1). Endocrine responses to stress are mediated by activation of two major endocrine pathways: The hypothalamic-pituitary-adrenocortical system and the
sympathetic-adrenomedullary system. Hypothalamus plays a central role in mediating and controlling the stress response. Several hormones are involved in the neuroendocrine response to stress such as ACTH, human growth hormone (hGH), vasopressin, TSH, Cortisol, insulin, glucagon, prolactin, aldosterone, renin, LH, FSH, adrenaline and noradrenaline (1,2). Stress hormone secretion is not only influenced by trauma itself, but also by direct pharmacological effects of certain anaesthesia (3). This study was planned to investigate the endocrine stress response occurring during total intravenous anaesthesia (TIVA) provided by propofol-alfentanil and air-oxygen by comparing with inhalation anaesthesia provided by halothane and N₂O-oxygen mixture (IA).

**Methods**

**Patients**

After obtaining written informed consent, we examined ASA 30 adult patients to undergo open urethralolithotomy. Patients with known endocrine or neurological disorders and those with conditions likely to alter stress hormones, such as pain, hypovolaemia and hypothermia were excluded from the study.

**Procedures**

All patients were starved for six hours prior to procedure. In this period, 500-700 ml of NaCl 0.9% were infused to compensate the fluid loss. Central venous pressure and urine output were measured using subclavian catheter and urine catheter respectively to ensure that the patients were normovolemic pre, intra and postoperatively.

Patients were divided randomly into two groups (TIVA and IA). Total intravenous anaesthesia with propofol-alfentanil was applied to TIVA group, whereas the IA group received inhalation anaesthesia with halothane and N₂O-oxygen by comparing with inhalation anaesthesia provided by halothane and N₂O-oxygen mixture (IA).

In TIVA group (n = 15); alfentanil 25 µg kg⁻¹ was given within two minutes and propofol 2 mg kg⁻¹ within 30 seconds intravenously for induction. Anaesthesia was maintained with the infusion of alfentanil 10 µg kg⁻¹ min⁻¹ for the first 10 minutes and 0.5 µg kg⁻¹ min⁻¹ thereafter and with propofol 10 mg kg⁻¹ h⁻¹ for the first 10 minutes, 8 mg kg⁻¹ h⁻¹ for the next 10 minutes and 6 mg kg⁻¹ h⁻¹ thereafter by two separate infusion pumps (IVAC 770, SAN DIEGO, CALIFORNIA). Ventilation was provided by the oxygen-air mixture, using a ventilator (Newport Breeze E-150, NEWPORT, CALIFORNIA).

In IA group (n=15): Anaesthesia was induced with thiopentone 6 mg kg⁻¹ and was maintained with halothane 1% and N₂O 66% in oxygen as end-expiratory concentrations.

Atracurium administration was discontinued 20 minutes before the expected end of surgery.

Atracurium was administered with a bolus dose of 0.5 mg kg⁻¹; followed by an infusion with a rate of 0.4 mg kg⁻¹ h⁻¹ atracurium for the neuromuscular block (IVAC 770, SAN DIEGO, CALIFORNIA). When the twitch depression reached 90% (TOF-GUARD INMT, ODENSE, DENMARK), endotracheal intubation was performed. In both groups, ventilation was mechanically conducted with IPPV in such a way that the values would be : ET_co₂: 34±4 mmHg and FiO₂:0.3. The adequacy of anaesthesia was evaluated according to the presence of significant variations in mean arterial pressures and the heart rates (>±25, <±25), at the same time to the presence of the symptoms of autonomic nervous system stimulation such as sweating and lacrimation.

Atracurium administration was discontinued 20 minutes before the expected end of surgery.
Cessation of alfentanil infusion was 15 minutes before the end, whereas propofol infusion was stopped during the last skin sutures. Neostigmin 0.07 mg kg\(^{-1}\) and glycopyroíate 0.01 mg kg\(^{-1}\) were administered intravenously to the patients with continuing neuromuscular blockage. If spontaneous ventilation was still inefficient (ET\(\text{CO}_2\) > 45 mmHg), naloxone was given in TIVA group according to the patient's response. In both groups, postoperative analgesia was evaluated by Visual Analogue Scale (VAS: 0-10 cm). Patients received meperidine hydrochloride 50 mg intramuscularly for postoperative analgesia when VAS > 5 cm. No patient received blood or blood components during the study.

**Monitorization**

Mean arterial pressure, central venous pressure, heart rate, ECG, transcutaneous oxygen saturation (Sp\(\text{O}_2\)), inspiratory oxygen (Fi\(\text{O}_2\)), end-tidal carbon dioxide concentrations (ET\(\text{CO}_2\)), end-tidal N\(_2\)O concentrations (ET\(\text{N}_2\)\(_0\)), end-tidal halothane concentrations (ET\(\text{Halothane}\)) and rectal temperature were monitored by Datascope passport, (PARAMUS, NEW JERSEY) and Datex capnomac ultima (HELSINKI, FINLAND).

**Blood sampling**

Serum Cortisol, ACTH, human Growth hormone (hGH), prolactin, insulin and blood sugar concentrations were measured at 10.00 a.m. on the day before surgery (control) (T\(_1\)), 30 (T\(_2\)) and 60 (T\(_3\)) minutes after intubation and 120 minutes after the end of surgery (T\(_4\)) by radioimmunoassay. All samples were taken between 8.00 and 12.00 a.m.

**Data analysis**

Patient's data, duration of anaesthesia and control values of stress parameters were analysed with the Student's t test. Blood sugar and endocrine data within group were statistically evaluated with repeated measures analysis of variance test. Comparisons between the groups were analysed with Mann Whitney U test. p<0.05 was considered significant. All statistical analysis were performed by statistical package for social sciences for windows V\(^{TM}\) (SPSS INC., 1989-1992).

**Results**

**Patient data**

The patients' data, duration of anaesthesia and control values of stress parameters are shown in Table 1. There was no significant difference between two groups. The changes in hemodynamic variables, body temperature and other parameters monitored were within the acceptable clinical limits during this study. Blood loss did not exceed 200-300 ml, and neither blood nor blood components were given.

**Endocrine data**

Cortisol. Cortisol concentrations increased promptly at T\(_1\) and T\(_2\) after the induction of anaesthesia, reached a maximum at T\(_4\), in both groups (p<0.05) (Figure 1). There was no significant difference in Cortisol concentrations between two groups in the course of the study.

ACTH. ACTH concentrations increased immediately after the induction of anaesthesia (T\(_1\)), remained elevated in the postoperative period (T\(_3\)) in both groups. In IA group these increases...
DOES INTRAVENOUS ANAESTHESIA WITH PROPOFOL-ALFENTANIL ATTENUATE THE STRESS RESPONSE?

were higher than in TIVA group at T₃ (p<0.05) (Figure 2).

hGH. hGH concentrations did not change during the study period in group TIVA, whereas they increased at T₂, T₃ in IA group (p<0.05) and returned to initial level after the end of surgery (T₄). In IA group, hGH concentrations were higher than in TIVA group during the operation (T₂, T₃) (Figure 3).

Prolactin. In both groups, prolactin concentrations reached the maximum levels immediately after beginning of the surgery (T₂), remained elevated in the intraoperative period (T₃) and these increases started to decrease in the postoperative phase (T₄) (p<0.05). There was no significant difference in prolactin concentrations between IA group and TIVA group (Figure 4).

Insulin. Insulin concentrations did not change within time in both groups although there was a slight tendency to decrease (Figure 5).

Blood sugar. Blood sugar levels increased according to initial values and remained elevated during the study in both groups (p<0.05). There was no significant difference between the two groups (Figure 6).

**Discussion**

Endocrine response to stress is associated with perioperative morbidity or mortality (4,5). The response to stress is mediated by complex intrac-
Does intravenous anaesthesia with propofol-alfentanil attenuate the stress response?

Tions between the endocrine, immune, nervous and hematopoietic systems. Preoperative fear, anxiety, starvation, length of surgery, type of surgery, hemorrhage, septic shock, hypothermia, premedication and anaesthetic technique are various factors affecting the magnitude of the hormonal response (6).

Parameters like Cortisol, ACTH, hGH, prolactin, insulin and blood sugar are studied in this study in order to show the endocrine response to stress. Adrenaline, noradrenaline, TSH, LH, FSH, vasopressin, renin, aldosterone, cytokines-interleukins and TNF are some other parameters which indicate the response to stress (1,2). However, these parameters are not investigated in this study due to our limited laboratory conditions and not to increase the cost of study.

The endocrine response to anaesthesia and surgery described in this study was characterized by increases in serum Cortisol, ACTH, prolactin and blood sugar concentrations, while insulin concentrations remained unchanged. ACTH and hGH responses were less pronounced by TIVA compared with IA. hGH and prolactin concentrations returned to the initial levels in the postoperative period.

The anesthesiologists must deal with the consequences of the body response to stress and must also be aware of the effects of anaesthetics on the response to stress (7). In recent years, many studies dealing with the endocrine response to surgical trauma and anaesthesia have been published (7-9). Inhalational agents, in general, are unable to suppress any of the response to stress (7,10). However, studies using high doses of opioids (11,12) and extradural anaesthesia have demonstrated marked suppression in the endocrine stress response (13). Recently it has been shown that Cortisol response to abdominal surgery is less with intravenous anaesthesia provided by propofol-alfentanil than with inhalational anaesthesia provided by isoflurane and prolactin increases in both groups (14). In our study, Cortisol and prolactin increased less in TIVA group than in IA group. This increase in the prolactin levels was higher during surgery than that in the postoperative period. Sassin and colleagues have reported that the prolactin levels were highest during the sleep period (15). It has also been demonstrated that the administration of opioid receptor agonists is one the factor increasing serum prolactin levels (16) and that opioid regulation of prolactin secretion in human is unclear (17). According to our findings, the prolactin levels have been found to be lower in TIVA group receiving alfentanil which is an opioid. It was probably because of the low doses of alfentanil.

Hall and Desborough have emphasized that the normal feedback mechanisms which controlled hormonal secretion were less sensitive in the perioperative period, for example, an increased circulating Cortisol was unable to suppress ACTH secretion and the hyperglycemia was unable to stimulate insulin secretion (18). Recent data has suggested that anaesthesia may have a role in inhibiting insulin secretion (19). According to our findings, insulin levels did not change even though blood sugar increased and Cortisol secretion was unable to suppress the ACTH secretion as they were expected before.

In conclusion, our opinion is that; TIVA provided by propofol-alfentanil would better attenuate endocrine changes occurring in response to anaesthesia and surgical stress than the inhalation anaesthesia provided by halothane-N,0. However, this conclusion should be correlated with patient outcome by further studies.
