Endometriosis is the presence of the endometrial glands and stroma outside of the endometrium, pelvic or extra pelvic sites in 1860. The endometrial gland and stroma can spread to the serviks, vagina, perineum or even spread to the urinary tract, gastrointestinal tract, thorax and nervous system. The cases of extra-pelvic endometriosis are usually coincidental. Because of unusual presentation, the exact diagnosis of endometriosis may result in delay. We are reporting such an unusual case of endometriosis and surgical approach at this important sensory area hoping to increase awareness of this rare condition.

**CASE REPORT**

A 32-year-old female presented with a progressively enlarging labial mass over 9 months. She married for three years, with no medical and family history, nulligravida, with regular menstrual cycles, using oral contraceptive pills for contraception. She reported that; the mass appeared to be more prominent and tender during menstrual period. She did not complain of dysmenorrhea, dyspareunia or chronic pelvic pain. There was no history of any operation, trauma and bowel or bladder complaints. Pelvic examination revealed a 5cm x 4.5cm x 6cm, solitary and mobile cystic mass in her left labium minus (Figure 1a). Our preoperative diagnosis was a labial mucoid cyst. General physical examination and the transvaginal ultrasonographic (TVUS) examination were normal. There was no fluid or mass in the ab-
dominal cavity and pouch of douglass on TVUS. Perineal ultrasonography on vulva was performed and only fluid filled, regular edged cyst observed just under localized vulvar epithelium. There was no solid component and septa in the cyst. So, we didn’t need Magnetic Resonance Imaging. Inspection of the vagina using a speculum as well as rectovaginal digital examination was uneven. Initially our diagnosis was a labial mucoid cyst and planned cystectomy under spinal anesthesia. Written informed consent and ethical approval were obtained from the patient for publication of this case report and taking images. Operation field was prepared with povidone-iodine solution at dorsolithotomy position. The lidocaine with 1/1000 adrenaline infiltrated with injectable saline in order to hydrodissection. The incision was made on inter labial sulcus and during the operation, we encountered 5cm x 4.5cm x 6cm, encapsulated, regular edges cyst wall just under the subepithelial layer (Figure 1b). While dissection, the capsule was ruptured and a chocolate like fluid spread on the operation field. Totally the cyst capsule was removed with sharp and blunt dissections. The final diagnosis with pathology was endometrial epithelium, endometrial glands, and hemosiderin-laden macrophages present in labial tissue. At the patient’s 8-week postoperative evaluation, she had no recurrence cyst or tender at menses at this region. She reported no decreasing about her sexual arousal. The patient didn’t receive extra treatment like Luteinizing Hormone Releasing Hormone (LHRH) analogues for postoperative good evaluation but she continued to take oral contraceptive pills for contraception.

DISCUSSION
Endometriosis is a immune-dependent genetically determined disease, which appears as an endometrioid tissue that grows outside the uterus affecting 1-7% of the population. Clinically, endometriosis symptoms can be related both intra- and extra-genital organs. There is a case report about endometriosis of vulva and perineum in the literature. Vulvar endometrial lesions usually occur after surgery or trauma. However, spontaneously vulvar endometriosis reported only two cases in the literature. The most common sites are episiotomy scars, Bartholin’s gland and more rarely labia majora or labia minora. Spontaneous vulvar location of endometriosis may be explained by the lymphovascular dissemination theory.

sites endometriomas are often confused with granuloma, hematoma, keloid, incisional hernia, vascular formation, sebaceous cyst, lipoma, or tumors and so patients often report general physicians, surgeons, or dermatologist because of atypical presentation and sometimes resulting delay in diagnosis. Endometriosis at extra-pelvic sites often presents unusual symptoms. In our case, endometriosis may be suspected only due to the exacerbation of mass size during menses. Although many of the cases are incidental, histology is landmark of the diagnosis. The accurate diagnosis of endometriosis involves the presence of two or more of these histologic results: endometrial epithelium, endometrial glands, endometrial stroma, and hemosiderin-laden macrophages. Histological examination has also identified the labia minora as specialized, sexually responsive, highly vascular, folds of tissue with an abundance of neural elements. Because of that, the surgeon should avoid unnecessary dissection of the labia minora. It makes sense to preserve important sensory areas during surgery. Preoperative sensory mapping of the labium and clitoral hood may prevent nociceptive injury, particularly in regions important in arousal pathways. The typical midline incision risks disruption of the densely innervated clitoris and the labia minora. The sensory mapping technique leads to a lateral approach, minimizing this risk. Based on Wu et al’s experience, in most instances, the safe zone falls at the junction of the labia majora and minora (the “inter-labial sulcus”), which is generally immediately before the transition to hairy skin. We made the skin incision at interlabial sulcus and postoperative 8 months evaluation the patient reported no decreasing about her sexual arousal.

So, any vulvar lesion, regardless of its size, location and symptomps can be related to endometriosis. Surgical resection is a good approach to relieve the symptoms and provide histological proof. The surgeon should make sense to preserve important arousal area during the surgical resection.

Informed Consent
Written informed consent was obtained from the patient for publication of this case report and accompanying images.

Source of Finance
During this study, no financial or spiritual support was received neither from any pharmaceutical company that has a direct connection with the research subject, nor from a company that provides or produces medical instruments and materials which may negatively affect the evaluation process of this study.

Conflict of Interest
No conflicts of interest between the authors and / or family members of the scientific and medical committee members or members of the potential conflicts of interest, counseling, expertise, working conditions, share holding and similar situations in any firm.
